Analysis of tumorigenicity in nude mice.

All experimental procedures involving animals were in accordance with the Guide for the Care and Use of Laboratory Animals (NIH publications nos. 80-23, revised 1996) and were performed according to the institutional ethical guidelines for animal experiment [1-3]. HepG2.2.15 and HepG2 cells were transfected *in vitro* with 100 nM (final concentration) siCtrl or siPCNAP1 by using Lipofectamine RNAiMAX (Invitrogen, Carlsbad, CA). At 48 hours after transfection, 10^7 viable cells were injected subcutaneously into the right flanks of 4- to 6-week-old male BALB/c athymic nude mice, six mice per group. Tumor growth was measured after 10 days from injection and then every 5 days. At 30 days after injection, mice were sacrificed and tumors were weighed after necropsy. Tumor volume (V) was monitored by measuring the length (L) and width (W) with calipers and calculated with the formula [4] * 0.5. The Institute Research Ethics Committee at the Nankai University approved the study protocol.

Analysis of cell proliferation.

The protocol was described previously [1, 5-8]. Hepatoma cells were seeded into 96 well plates (2000 cells/well) for 12 hours before transfection and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay was used to assess cell proliferation every day from the first day until the third day after transfection. 5-ethynyl-2'-deoxyuridine [9] incorporation assay was carried out using the Cell-LightTM EdU imaging detecting kit according to the manufacturer's instructions (RiboBio, Guangzhou, China). For colony formation analysis, 48 hours after transfection, 1000 viable transfected cells (HepG2.2.15,

HepG2 and HepG2-X cells) were placed in 6-well plates and maintained in complete medium for 2 weeks. Colonies were fixed with methanol and stained with methylene blue.

Co-immunoprecipitation assays.

The co-immunoprecipitation (co-IP) protocol was described in detail in previously published articles [10]. The lysates harvested from Hepatoma cells transfected with different regiments as the manufacturer's instructions were then subjected to overnight immunoprecipitation at 4°C using 2–5 g of antibodies listed in Table S4. Negative controls with IgG were included in each experiment. Immune complexes were incubated with protein A/G agarose beads at 4°C. The precipitates were washed six times with ice-cold lysis buffer, resuspended in the PBS, and resolved by SDS-PAGE followed by Western blot analysis.

Immunohistochemistry.

The tumor tissue from nude mice were fixed and embedded with paraffin after those mice were sacrificed. Immunohistochemical staining of samples were performed as previously reported [1, 6-8] and the primary antibody of rabbit anti-Ki-67 was used (Table S4).

TCGA database

Public TCGA (<https://portal.gdc.cancer.gov/>) data repositories for liver hepatocellular carcinoma (LIHC) (Cancer Genome Atlas Network, 2014) were used to analyze the expression of PCNA and miR-154.

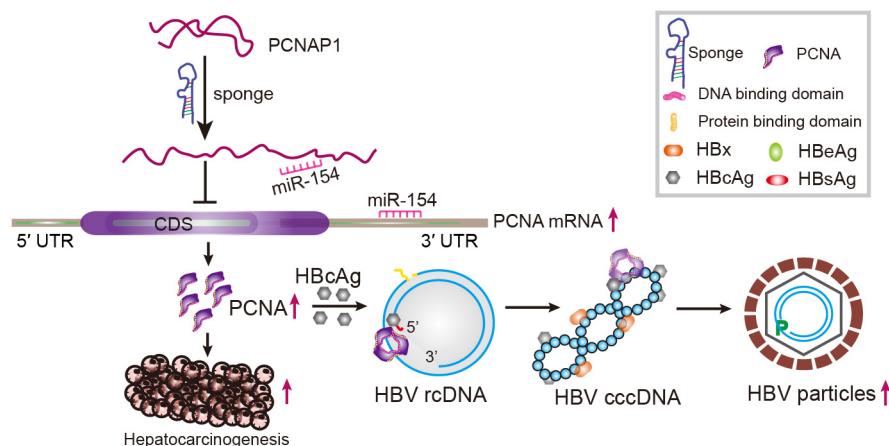

Figure S10. A model of PCNAP modulating HBV replication and enhancing hepatocarcinogenesis. In this model, PCNAP1/PCNA signaling promotes HBV replication by modulating HBV cccDNA accumulation. PCNAP1 as a natural sponge of miR-154 regulates its ancestral PCNA. HBc-recruited PCNA binds to HBV cccDNA, leading to HBV replication and cccDNA accumulation. Meanwhile, PCNAP1/PCNA signaling promotes hepatocarcinogenesis.
