Supplementary Methods

Sample preparation and genomic profiling

All tumor tissues (fresh-frozen, FF; or formalin fixed paraffin-embedded, FFPE) obtained from participants were reviewed by two independent pathologists before sample disposal to confirm the pathologic diagnoses of biliary tract carcinomas (BTCs). Serial sections on tissue slides was performed to evaluate tumor content and percentage. Only samples with estimated tumor purity >20% on histopathologic assessment were further subjected to genomic profiling. Tumor purity assessed in our study is the proportion of cancer cells in the tissues. Tumor tissue section from each patient was hematoxylin-eosin (HE) stained, and the proportion of cancer cells was then estimated by pathologists. For sections with tumor purity over 20%, bulk tumor tissues were subjected to extract DNA and sequencing. For those tumor tissues with purity less than 20%, micro-resected tumor section was performed to remove non-cancerous cells and stroma to improve tumor purity. DNAs were extracted from paired tumor and blood samples using DNA Extraction Kits (Qiagen). DNAs yield and quality were quantified using the Qubit 3.0 (Invitrogen) and NanoDrop 2000 (Thermo Scientific) and the integrity was further visually inspected by agarose gel electrophoresis.

Genomic alterations profiling was performed in 2 major next-generation sequencing (NGS) platform, including whole-exome sequencing (WES) and a custom hybridization capture-based targeted panel sequencing (TPS)[1] provided by Origimed (Cancer Sequencing YS panel, CSYS, Shanghai, China). WES libraries were prepared from DNA extracted from tumor and normal samples using the Agilent's SureSelect Human All Exon V6 Kit (Agilent Technologies Inc.), and the sequencing was conducted using the Illumina HiSeq XTEN platform for paired-end 150bp reads. For CSYS platform, 50–250ng DNA was used to construct libraries, targeted genomic regions were hybrid-captured, and sequence reads were generated using Illumina (San Diego, CA) instruments with the referred procedures followed the steps described in Frampton et al,[2].

WES data analysis

Somatic mutation calling and filtering

Paired-end reads from paired tumor and normal-control samples were aligned to the human reference genome (GRCh37) using the Burrows-Wheeler Aligner (BWA) (version 0.7.10)[3]. Somatic mutation calling was processed using GATK (version 3.7)[4] followed the GATK Best Practices by using its Mutect2 function with duplicate and unmapped reads removed. A stringent downstream filter comprised of the following criteria was used to obtained high quality somatic variants: Variant Allele Fraction (VAF) $\geq 5\%$ with >5 variant supporting reads in the tumor sample, and VAF $< 1\%$ in the normal-control samples; a minimum of 5X coverage; strand bias ≤ 0.95 . Variants with PASS tag was retained and annotated by ANNOVAR (version: 2018-04-16)[5] using multiple specific databases (e.g. ExAC03, dbNSFP33a, ClinVar-20170130, avsnp150, Cosmic70). To make a possible comparison with target sequencing, non-coding variants in the introns, upstream or downstream of coding regions in 3'- and 5'-UTRs, and in intergenic regions were discarded.

Tumor mutation burden (TMB)

TMB analysis of WES data was performed followed with Chalmers et al,[6]. Briefly, all base substitutions and indels identified by WES in the coding region of genes as non-synonymous alterations, were all counted, except alterations listed as known somatic alterations in COSMIC or truncations in tumor suppressor genes were not counted. Known germline alterations in dbSNP or occurring with two or more counts in the ExAC database were not counted. TMB was calculated as the total number of mutation counts divided by the size of the coding region of the whole-exome territory.

Analysis of significantly mutated genes

MutSigCV (version 1.41)[7] was performed on the somatic variations of WES data to identify the significantly mutated genes that were mutated more often than expected by chance. MutsigCV's q-value < 0.1 was taken as threshold to detect significantly mutated genes. Populational frequencies of mutated genes was calculated by integrating WES and TPS samples together. In addition, mutual co-occurrence and exclusive event analysis on top 20 significantly mutated genes was performed by "somaticInteractions" function from Maftools (version 2.2.10)[8], using pair-wise Fisher's Exact test to detect such significant pair of genes. Then "oncostrip" function was used to visualize mutually exclusive set of genes for *TP53* and *KRAS*.

Somatic copy-number alterations (SCNAs) calling

According to the Agilent Target BED file, copy number for each segment was first analyzed by Control-FREEC (version 11.4)[9] and segments with same copy number were merged together to

generate a unique segment file. GISTIC2 (version 2.0.23)[10] was then used to calculate significant copy number gains and losses at a confidence level 0.99. Focal amplifications and deletions were selected using a threshold of GISTIC's q-value ≤ 0.01 .

Identifications and annotations of germline variants

Germline variants were identified using GATK (version 3.7) and its HaplotypeCaller function in single-sample mode with duplicate and unmapped reads removed. Variants were then filtered using VariantFiltration function of GATK with parameters "DP <4 || QD <2.0 || FS >60.0 || MQ <40.0 || MQRankSum <-12.5 || ReadPosRankSum <-8.0" and "DP <4 || QD <2.0 || FS >200.0 || ReadPosRankSum <-20.0" for SNVs and indels, respectively. Furthermore, to exclude potential tumor-in-normal contamination, germline mutations with VAF in normal-control sample <30%, and co-localizing with any known somatic mutation, which germline variants located at the same protein residue as recurrent ($n \geq 3$) somatic mutations in TCGA MC3 MAF[11] were further filtered. After the filtration, variants annotations were firstly obtained by ANNOVAR (version: 2018-04-16), and the evidence for pathogenic variations mainly derived from the public databases, including the Human Gene Mutation Database, Clinvar, Sorting Intolerant From Tolerant (SIFT), and the standard from American College of Medical Genetics (ACMG). A further manual review was performed to reduce the false positive variants.

Determination of MSI status

Microsatellites in the human reference genome (GRCh37) was identified using RepeatFinder (version 1.0)[12] with default parameters. To detect the microsatellite instability status, MANTIS (version 1.0.4)[13] was used with modified parameters "-mrq 20.0 -mlq 25.0 -mlc 20 -mrr 1" to fit for the whole-exome data, taken both tumor and non-tumor bam files as inputs. Any Step-Wise Difference (DIF) value calculated by MANTIS greater than or equal to 0.4 is treated as unstable. For 160 BTCs samples, only one patient was classified as MSI-H tumor, and MSI-PCR testing as the gold standard method was also performed to confirm the MSI-H status in tumor tissues.

TPS analysis for detecting somatic alterations

The raw sequencing data underwent stringent quality control of read depth and ratio of target capture. Data quality was inspected and controlled by examining sequencing coverage and uniformity, and a suite of customized bioinformatics pipelines was applied for discovery of SNVs,

short and long indels, SCNAs and gene rearrangements. The bioinformatics pipelines of CSTS have been described in our previous reports[1].

TMB was calculated from TPS data for each sample by counting the number of somatic mutations, including coding SNVs and indels, per megabase (Mb) of the sequence examined. Known somatic mutations in the Catalog of Somatic Mutations in Cancer (COSMIC) and known germline polymorphisms in the U.S. National Center for Biotechnology Information's Single Nucleotide Polymorphism Database (dbSNP) were not counted[6].

TPS panel designed 572 microsatellite loci (MSLs) targeted region as candidate MSI markers, which were done as previously described[13,14]. Using custom predictive model analyzed by a random forest algorithm combined with an orthogonal validation of PCR testing or IHC method as the gold standard, MSI status for each tumor sample could be judged. PCR products were analyzed by Sanger sequencing using an ABI 3730 Genetic Analyzer (Thermo Fisher Scientific, Waltham, MA).

Finally, all the detected mutations were compared with our in-house database of genomic changes specific to clinical annotation. A manual review process was performed to ensure no false positives or mistakes in clinical annotations, including complex variant curation and clinical relevance inference based on our in-house database. Based on the annotated mutations, a succinct report with relevant references to literature and clinical trials was generated.

Identification of hypermutated tumors

To determine a threshold of hypermutation in BTCs, a segmented linear regression analysis or "broken-stick analysis" was performed on the mutation burdens from WES cohort and TPS cohort, which refers to method from Campbell's colleagues[15]. Briefly, using the R package "Segmented", an iterative process was used to determine segment breakpoints at which a statistically significant change in the slope of adjacent regression lines occurred[16]. Consequently, the threshold was determined to 9.36 Mut/Mb in WES and 16.1 Mut/Mb in TPS, respectively.

Mutational landscape construction

A mutational case was defined as sample with no less than one non-silent mutation in coding region or SCNAs detected in individual genes. We determine 68 potential driver mutation genes of BTCs (Supplementary Table S4) as following: (1) genes that simultaneously captured by both WES and

CSYS platform; (2) significantly mutated genes identified by MutSigSV from our WES data; (3) recurrent mutations summarized from three previous studies which investigated the genomic landscape of BTCs, including Nakamura et al[17], Jusakul et al[18], and Montal et al[19]; (4) Tier1 cancer-related genes presented in COSMIC Cancer Gene Census database (version 91, <https://cancer.sanger.ac.uk/census>). The mutational landscape was constructed according to the populational frequencies (>5%) with a slight modification and integrated the mutations of *IDH2* and *MUC4* which showed significantly different rate as comparing with previous cohorts. The mutational spectrum was visualized by Maftools (version 2.2.10).

Mutations enriched for oncogenic pathways

Recurrent alterations of BTCs presented in Figure 1C could be roughly classified into four major functional families, that are cell cycle/cyclins genes, receptor tyrosine kinases genes, chromatin-modifying genes and others. Furthermore, ten curated pathways with oncogene and tumor suppressor gene information were retrieved from a study of TCGA program[20]. The mutational map of these 10 pathways was constructed according to the paper with a slight modification by integrating the description of percentage of mutational cases for each subtype of BTCs (Supplementary Figure S5).

Determining the scope of DNA damage response (DDR) genes

The scope and definition of DDR genes were collected from Human DNA Repair Genes (<https://www.mdanderson.org/documents/Labs/Wood-Laboratory/human-dna-repair-genes.html>). As most DDR genes have not yet been determined to have oncogenic or pathogenic effects in BTCs, we narrowed the scope of DDR genes into 47 coding genes that could be captured by both WES and CSYS platform (Supplementary Table S6), listing as: *TP53*, *MUTYH*, *APEX1*, *PARP1*, *PARP2*, *PARP3*, *MGMT*, *MSH2*, *MSH6*, *MLH1*, *PMS2*, *ERCC1*, *RAD51*, *RAD51B*, *RAD51D*, *XRCC2*, *XRCC3*, *RAD52*, *RAD54L*, *RAD54B*, *BRCA1*, *RAD50*, *MRE11A*, *NBN*, *FANCA*, *FANCC*, *BRCA2*, *FANCD2*, *FANCE*, *FANCF*, *FANCG*, *BRIP1*, *FANCL*, *FANCM*, *PALB2*, *RAD51C*, *PRKDC*, *POLB*, *POLD1*, *POLE*, *FEN1*, *BLM*, *ATM*, *RECQL*, *ATR*, *CHEK1* and *CHEK2*.

Mutational signature analysis and identification of aristolochic acid (AA) signature

Mutational signatures were inferred for ICC samples performed WES from our cohort. Firstly, we excluded 4 hypermutated ICCs as considering hypermutated tumors has been demonstrated to have significantly different substitution patterns. Next, the 96 mutational subtypes generated from somatic SNVs based on 6 single-base substitutions (SBSs, C>A, C>G, C>T, T>A, T>C and T>G) in 16 possible combinations of neighboring bases for each SBS were used as input data to infer their contributions to observed mutations. We implemented a non-negative matrix factorization (NMF) approach[21] to decipher the mutational signatures (Signature A, B, and C) of all samples with the number based on the signature stability and Frobenius reconstruction errors. Finally, three mutational signatures (A, B, and C) were linked to the known COSMIC cancer signatures (<https://cancer.sanger.ac.uk/cosmic/signatures>) with comparing cosine similarities to infer their exposure contributions.

Mutational signature activity (mSigAct, v2.0.0-branch) was applied to assess presence of the AA signature in all ICC samples. The mSigAct software[22] provided a signature presence test to infer whether the observed mutation spectrum could be better explained with a contribution from the AA mutational signature (COSMIC signature 22) than without it and compared them with a likelihood ratio test. The null hypothesis was that the mutational counts were generated without the AA signature and the alternative hypothesis was that they were from the AA signature. The test was then carried out by a standard likelihood ratio test on these two hypotheses. The mSigAct revealed strong evidence of AA exposure with FDR < 0.05.

Immunohistochemistry for expressions of MMR genes

Whole sections from available FFPE of BTCs tissues were prepared into to 4 or 5 µm-thick on glass slides. For samples identified as MSI-H tumors, the primary antibodies used were anti-MSH2 (Invitrogen, clone 25D12), anti-MSH6 (Ventana, clone 44), anti-MLH1 (Ventana, clone M1) and anti-PMS2 (Agilent Dako, Clone EP51). The secondary antibodies were added to all sections, including the negative control slides. During interpretation, loss of nuclear staining in the tumor cells with positively stained internal control was counted as an abnormal result for 4 MMR genes.

Supplementary Figures

Figure S1. Correlation analysis of alterations in cocaptured genes between whole-exome sequencing (WES) and targeted panel sequencing (TPS). (A) Linear correlation between the variant allele fractions of cocaptured somatic single-nucleotide variants (SNVs, blue line) and indels (dark line) derived from WES and those derived from the TPS panel. (B) Identification of copy-number variants (CNVs) in individual genes from WES and TPS. The dashed line indicates the diploid copy-number (normal), and the vertical axis represents the number of copy-number gains (red) or copy-number losses (blue).

Figure S2. Distribution of somatic tumor mutation burden (TMB) and differences among the three subtypes of biliary tract cancer. (A) Distribution of TMB assessed by WES (top) or TPS (bottom) for each patient highlights the hypermutated group. Hypermutated cases are separated on the left, and the most drastic change point in the mutation rate (vertical dashed line) was chosen as the cutoff to discriminate hypermutated cases from non-hypermutated cases. (B) Linear correlation between TMB evaluated from WES and that evaluated from TPS. (C-D) Landscape of TMB across the major tumor types in WES data (C) or TPS data (D). The median level of TMB for each tumor type and in our cohort is highlighted.

Figure S3. Somatic interactions of cooccurring or exclusively occurring mutations among the top 20 significantly mutated genes in 803 BTC patients. (A) Pairwise Fisher's exact tests were performed to detect significant pairs of genes. The cooccurring relationships are colored by a green box, while the exclusively occurring mutations are colored by a pink box. (B) *TP53* mutations are exclusive to alterations in *ARID1A*, *MUC4*, *IDH1* and *EPHA2*. (C) *KRAS* mutations are exclusively associated with alterations in *LRP1B*, *TERT*, *PIK3CA*, *IDH1* and *EPHA2*.

Figure S4. Integration of somatic mutations and SCNAs to decipher the mutational landscape of BTC patients. Pathway components and interactions in the ten selected oncogenic pathways are plotted. Somatic alteration (mutation and CNV) spectra of components in these pathways among the three subtypes (ICC, ECC, and GBC). The numbers of altered samples in each subtype are labeled in the boxes, and the color intensity indicates the average frequency of the alteration in each subtype. The numbers of patients harboring altered pathways are compiled in the top left corner of the plot.

1 **Table S3.** Potentially actionable targets (PATs) in BTC patients.

Targets	Mutation Types	Drugs	OncoKB level	ESCAT tier
ABL1	E255K, E255V, F317C, F317L, F317L, F317V, F359C, F359I, F359V, T315A, Y253H, BCR-ABL1 Fusion	Bosutinib	2B	III-A
ALK	Fusions	Crizotinib	2B	III-A
BRAF	V600E	Encorafenib; Cetuximab; Binimetinib; Dabrafenib; Panitumumab; Trametinib	2B	III-A
BRCA1	Oncogenic Mutations	Olaparib	2B	III-A
BRCA2	Oncogenic Mutations	Olaparib	2B	III-A
CDK4	Amplification	Abemaciclib; Palbociclib	2B	III-A
EGFR	A763_Y764insFQEA	Afatinib; Erlotinib; Gefitinib	2B	III-A
ERBB2	Amplification, Oncogenic Mutations	Ado-Trastuzumab Emtansine; Trastuzumab; Carboplatin-Taxol Regimen	2B	III-A
KIT	C809G, D816A, D816E, D816F, D816G, D816H, D816N, D816V, D816Y, D820A, D820E, D820G, D820Y, N822H, N822I, N822K, N822Y, R796G, Y823D, T670I, V654A, D816, Oncogenic Mutations	Sorafenib; Imatinib	2B	III-A
MET	Amplification, D1010mut, Exon 14 Deletion, Exon 14 splice mutation, Y1003mut	Cabozantinib; Crizotinib	2B	III-A
PDGFR A	Oncogenic Mutations, D842V	Imatinib, Dasatinib	2B	III-A
RET	Fusions, Oncogenic Mutations	Cabozantinib; Vandetanib; LOXO-292	2B	III-A
TSC1	Oncogenic Mutations	Everolimus	2B	III-A
TSC2	Oncogenic Mutations	Everolimus	2B	III-A
FGFR2	Fusions	BGJ398; Debio1347; AZD4547; Erdafitinib	3A	I-B
IDH1	Oncogenic Mutations	BGJ398; Debio1347; AZD4547; Erdafitinib	3A	I-B
AKT1	E17K	AZD5363	3B	II-B
NTRK	Fusions	larotrectinib	3B	I-C
MSI-H	dMMR	pembrolizumab	3B	I-C
